

1 **YIELD AND FORAGE QUALITY OF SALTBUSH IRRIGATED WITH REJECT**
2 **BRINE FROM A DESALINATION PLANT BY REVERSE OSMOSIS**

3
4
5 **ABSTRACT** - Rural communities located in the Brazilian Northeast, especially in the
6 semiarid zone, live with water shortages resulting from erratic rainfall. This work proposes
7 the cultivation of saltbush (*Atriplex nummularia*) in the Rural Settlement Project of Boa Fé,
8 Mossoró/RN as alternative to the disposal of reject brine from a desalination plant on yield of
9 forage. The statistical design was a split-plot design, being four treatments at the plots, related
10 to levels of soil moisture by moisture from Field Capacity (FC) (100%, 85%, 70% and 50% of
11 FC) and in subplots and two levels of organic manure (without fertilized and fertilized) with
12 four replications. The variables of yield and forage quality of saltbush were analyzed. It was
13 observed that saltbush has a great production capacity in terms of fresh matter and drought for
14 saltbush under a level of 85% soil moisture in relation to the field capacity of soil, presenting
15 minimal loss of yield; however, this proved to be productive even with the dry soil. The total
16 yield was satisfactory, showing its viability for forage production.

21 **PRODUÇÃO E QUALIDADE FORRAGEIRA DA ERVA SAL IRRIGADA COM**
22 **REJEITO DA DESSALINIZAÇÃO POR OSMOSE REVERSA**

23
24
25 **RESUMO** - As comunidades rurais situadas no Nordeste brasileiro, em especial na região
26 semiárida, convivem com a escassez de água resultante da irregularidade das chuvas nesta
27 região. O presente trabalho propôs cultivar a erva sal (*Atriplex nummularia*) no Projeto de
28 assentamento Rural Boa Fé, Mossoró/RN como alternativa à deposição do rejeito salino para
29 a produção de forragem. O delineamento estatístico foi parcelas subdivididas, sendo quatro
30 tratamentos nas parcelas, referentes a níveis de umidade do solo tendo como base a umidade
31 na Capacidade de Campo (CC) (100%, 85%, 70% e 50% da CC) e nas subparcelas, dois
32 níveis de adubação orgânica (não adubado e adubado), com quatro repetições. Foram
33 analisadas variáveis de produção e qualidade da forragem da erva sal. Observou-se que, a erva

34 sal possui boa capacidade de produção de matéria fresca e seca sob um nível de 85% de
35 umidade do solo em relação à sua capacidade de campo, apresentando mínimas perdas de
36 rendimento, porém, mostrou-se produtiva mesmo com o solo mais seco. A produtividade total
37 foi satisfatória mostrando sua viabilidade para a produção de forragem.

43

44 INTRODUCTION

45

46 In the Brazilian Northeast, especially in the semiarid region, irregular rainfalls cause a
47 scarcity of shallow water deposits, resulting in a lack of water. In most rural communities of
48 this region, the existence of this phenomenon is remarkable. However, it results in problems
49 regarding the supply of drinking water. In view of this problem and the great potential
50 groundwater resources, the drilling of wells to pump these waters has become a viable
51 alternative commonly used for the irrigation of various horticulture areas through shallow
52 wells with a low construction cost but with relatively high salt concentrations (SOUZA et al.,
53 2009; DIAS et al., 2011; SOARES et al., 2015).

54 The drilling of wells has been used as a source of water for many rural communities of
55 this region. However, even with groundwater being identified as a viable alternative to ensure
56 access to water by rural communities in the Northeast, such sources of water present in most
57 cases use restrictions for human consumption because of salinity problems (MEDEIROS et
58 al., 2014; TERCEIRO NETO et al., 2014).

59 To minimize this problem, the Federal Government established the Freshwater
60 Program. Its main objective is to solve the lack of water supply in these communities by
61 installing and maintaining brackish water treatment stations (desalination plants) in rural
62 communities to treat water from wells (SOARES et al., 2006). In Mossoró, this program has
63 benefited about 50 communities.

64 Reverse osmosis is a technology widely used for the treatment of brackish water
65 (PORTO et al., 2006), with successful experiences in most locations where desalting water
66 treatment units are implemented. The use of reverse osmosis desalination has progressed

67 remarkably, and the market and its applications are being considerably expanded. However,
68 its economic aspect limits its expansion.

69 The deposition of the waste generated by treatment plants creates environmental
70 concerns because of its high soil or water polluting capacity, if the process is not done
71 correctly. In view of this, alternatives to this waste reuse are being studied. The use of
72 evaporation tanks, tilapia and shrimp breeding and cultivation of halophytes are current
73 alternatives more convenient to the destiny of this waste.

74 Regarding the cultivation of halophytes, *Atriplex nummularia*, also known as saltbush,
75 has excelled in Brazil, being the object of several studies. Because it is from arid regions,
76 *Atriplex* is especially important because it is able to produce and maintain an abundant
77 biomass even in high aridity and salinity environments (PORTO et al., 2006). It is important
78 to the phytoremediation process of soils affected by salts because it is convenient to the
79 requirements of this process; it produces an abundant biomass in soils with a high salt content
80 and tolerates drought, a common factor in arid and semi-arid areas (SOUZA et al., 2012).

81 From this perspective, this study aimed to use saline waste from a brackish water
82 treatment station located at the settlement Project Boa Fé (Mossoró, RN) for the irrigation of
83 saltbush (*Atriplex nummularia*) in order to evaluate its yield potential and forage quality.

84

85

86 MATERIAL AND METHODS

87

88 The experiment was conducted from September to December 2012 in the Settlement
89 Project Boa Fé, located along the BR 304 highway, rural zone of the municipality of Mossoró,
90 RN (geographical coordinates: 5°03'07.32" S and 37°20'22.42" W). The experimental area
91 was 180 m². It is located near a brackish water treatment station, facilitating handling the
92 saline waste to be used in research.

93 An irrigation system localized by gravity was chosen mainly because it does not require
94 electrical power to operate. Microtube emitters of 1.5 mm in diameter and 1.5 m in length
95 were used, resulting in an average flow rate of 5.0 L h⁻¹. In order to standardize irrigation,
96 both the irrigation hoses and the height of the water emission by the microtube were leveled
97 in the entire experiment area. The Christiansen Uniformity Coefficient (CUC) was calculated,
98 obtaining 93% uniformity.

99 A reservoir for waste storage to be used for irrigation, with a capacity of 1,000 L, was
 100 placed on a wooden structure at a 2.0 m height. It was installed in the center of the
 101 experimental area for a better distribution of irrigation water to plants. The chemical
 102 composition of the saline effluents used in irrigation is shown in Table 1.

103
 104 **Table 1.** Physical and chemical characteristics of the waste from water desalination used in
 105 the irrigation of saltbush.

pH	EC	K ⁺	Na ⁺	Ca ²⁺	Mg ²⁺	Cl ⁻	CO ₃ ²⁻	HCO ₃ ⁻	SAR ¹	Hardnes s	ΣCations	ΣAnion s
(water)	dS m ⁻¹	----- mmol _c L ⁻¹ -----				-----			-	mg L ⁻¹	--- mmol _c L ⁻¹ ---	
6,92	9,35	0,63	43,23	40,6 0	31,40	154,00	8,00	0,00	7,2	3600	115,96	162,00

106 ¹SAR = Na⁺/[(Ca²⁺ + Mg²⁺)/2]^{1/2}

107
 108 The experimental design was a split plot design with four treatments related to soil
 109 moisture levels based on moisture of Field Capacity (FC) in plots and subplots and two levels
 110 of organic fertilization, with four replications and two plants per subplot, totaling 64 plants.
 111 Based on the soil water retention curve, the voltage at field capacity was set to 6 kPa (60
 112 cm.ca) and the moisture in FC corresponded to 0.1456 cm³ cm⁻³. This voltage to determine
 113 FC in the experiment was adopted because the soil is granulometrically classified as sandy
 114 loam based on the function of the level of sand, silt and clay, which provides it with relevant
 115 drain power. In addition, several authors have postulated that the field capacity for tropical
 116 soils corresponds to voltages ranging from 6 to 10 kPa (MELLO et al., 2002; ANDRADE;
 117 STONE, 2011).

118 The effects of soil moisture were tested. The treatment of the plots was thus determined
 119 as T₁ = 100% of FC (0.1456 cm³ cm⁻³), T₂ = 85% of FC (0.1238 cm³ cm⁻³), T₃ = 70% of FC
 120 (0.1019 cm³ cm⁻³) and T₄ = 50% of FC (0.0728 cm³ cm⁻³). In the subplots, the treatments
 121 were without fertilization (F₀) and with an organic fertilizer (F₁). The organic feedstock was
 122 goat manure in the amount of 1.5 L per plant. The fertilizer was manually applied in a single
 123 dose on 15 cm-deep holes lateral to the plant.

124 Irrigation was performed daily. Based on the average readings from strains of water in
 125 the soil using tensiometers installed in each experimental plot, the current soil moisture was

126 obtained in each treatment using the soil water retention curve, allowing calculation of the
127 volume of irrigation necessary to maintain the soil moisture levels proposed by the treatments.

128 At the beginning of the experiment, all plants that were six months were cut,
129 maintaining the height and the crown diameter at 40 cm with the aid of a cylindrical-shaped
130 mold made of PVC with these dimensions in order to standardize the size of the plants, thus
131 facilitating the measurement of production at the end of the production cycle, the moment
132 when the cutting was carried out (harvest) after three months of cultivation.

133 Before the saltbush cutting, measurements of the crown diameter (CD) and plant height
134 (PH) of all plants were performed. Then, there was a cutting of all separated material into
135 leaves and stems to determine leaf fresh matter (LFM), stem fresh matter (SFM), and total
136 fresh matter (TFM) by the sum of LFM and SFM. Leaf dry matter (LDM) and stem dry
137 matter (SDM) were obtained after drying the material in an oven with forced air circulation at
138 65°C until constant weight. The total dry matter (TDM) was obtained by the sum of LDM and
139 SDM.

140 To evaluate the quality of the forage produced by saltbush, the percentage of dry matter
141 (DM) and levels of organic matter (OM), mineral matter (MM) and crude protein (CP) were
142 determined according to the methodology described by Silva and Queiroz (2002).

143 The data were submitted to ANOVA and regression for a quantitative treatment of plots
144 and to an average test of subplots using Assistat[®] software (SILVA; AZEVEDO, 2009).

145

146

147 RESULTS AND DISCUSSION

148

149 All growth and production variables of saltbush analyzed suffered significant linear
150 effects influenced by the soil moisture levels to which the plants were submitted. However,
151 organic fertilization did not significantly affect any of the variables; i.e., in production terms,
152 *Atriplex nummularia* did not respond to the fertilization performed in the present study,
153 proving to be a plant with rustic features in this respect (Table 2).

154

155 **Table 2.** Summary of the analysis of variance for the variables Leaf Fresh Matter (LFM),
156 Stem Fresh Matter (SFM), Leaf Dry Matter (LDM), Stem Dry Matter (SDM), Plant height
157 (PH), Crown Diameter (CD), Total Fresh Matter (TFM) and Total Dry Matter (TDM).

159

160 Plant height (PH) and crown diameter (CD) were reduced with decreasing soil moisture
161 according to the different percentages of field capacity of the soil to which they were
162 submitted (Figure 1). Considering the 40 cm cutting height to which the plants were
163 submitted at the beginning of the experiment, treatment T₁, at the end of three months of
164 culture, had an average PH of 83.13 cm, that is, an increase of 43.13 cm, a value higher than
165 the other treatments of 75.19, 71.75 and 69.75 cm for T₂, T₃ and T₄ respectively. These results
166 show the regrowth ability of *Atriplex nummularia*, a characteristic that influences its
167 production capacity. Souza et al. (2012) reported a 45.25 cm recovery of saltbush height in
168 relation to cutting height, which was 60 cm, after four months of cultivation in a sodium
169 saline soil under field conditions.

171

172 **Figure 1.** Linear regression equations relating plant height (PH) and crown diameter (CD) of
 173 saltbush (*Atriplex nummularia* L.) irrigated with waste from desalination differing in soil
 174 moisture level.

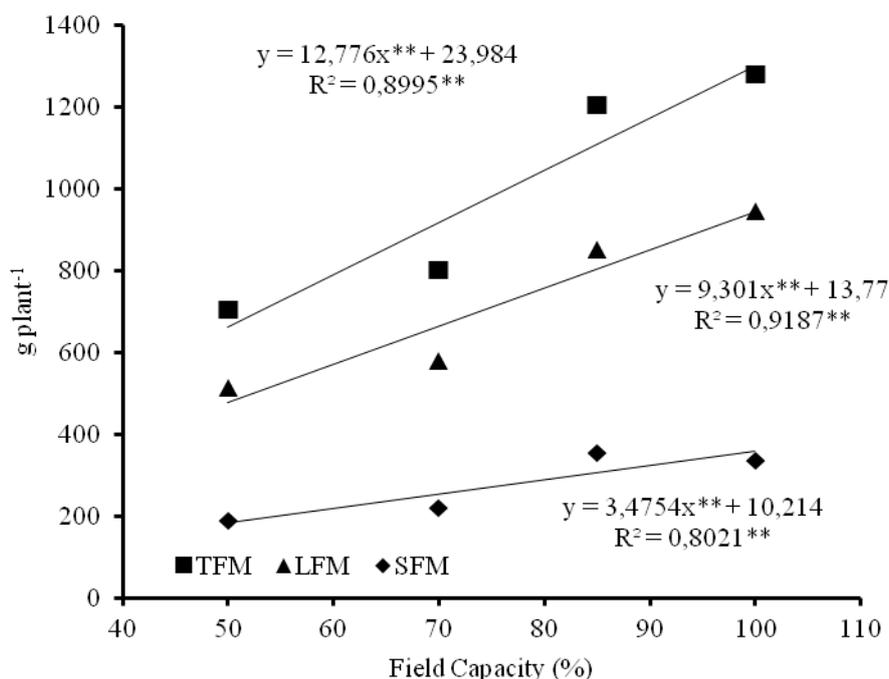

175

176 Moreover, the material resulting from regrowth showed to be tenderer for branches, not
 177 exceeding 1 cm in diameter, facilitating its use as forage for animals, in this particular case for
 178 goats. The literature shows that saltbush can reach over 2.0 m in height in the first year of
 179 cultivation and can reach 2–3 m in five years (PORTO et al., 2006).

180

181 CD had a similar behavior. However, differences between treatments were lower. T₁
 182 had a 75.16 cm CD average while the others were 67.94, 62.94 and 60.16 cm for T₂, T₃ and
 183 T₄ respectively. These results allow inferring that the spacing adopted for the cultivation of
 184 *Atriplex* can be modified according to the purpose of planting. When the aim is to cut saltbush
 185 to supply it fresh to animals, the silage or hay production may reduce the spacing, thereby
 186 increasing productivity. Vasconcellos (2011) obtained a productivity of 44,250 and 18,632 kg
 187 ha⁻¹ of Fresh and Dry matter respectively by using a 1 x 1 m spacing and irrigating the
 188 *Atriplex* with effluents from the creation of tilapia with wastewater from desalination and
 189 performing cutting only at six months of cultivation. In the present study, the cutting of
 190 saltbush was performed three months after the previous cut. This management allows using a
 191 more dense spacing. Moreover, the density may allow for a more efficient extraction of salts
 per soil area.

192 There was a reduction in Fresh Matter due to the reduction of soil moisture in the
 193 treatments, showing that *Atriplex nummularia*, despite being considered a halophyte resistant
 194 to drought, decreases its productivity when kept under reduced water conditions (Figure 2).

195
 196 **Figure 2.** Linear regression equations relating Leaf Fresh Matter (LFM), Stem Fresh Matter
 197 (SFM) and Total Fresh Matter (TFM) of saltbush irrigated with waste from desalination
 198 differing in soil moisture level.

199
 200 The greatest losses occurred in the leaves, where reductions in LFM were 9.91, 38.47
 201 and 45.48% in T₂, T₃ and T₄ respectively, compared to treatment T₁. This same tendency
 202 occurred with TFM. However, because of the behavior of T₂'s SFM, where there was no
 203 reduction in comparison to the control; the decrease in TFM for this treatment was only
 204 5.74% when compared to the control.

205 A similar behavior was observed by Souza et al. (2012). In their study regarding leaf
 206 fresh matter, the treatments with 75 and 95% of FC did not differ and surpassed the others (35
 207 and 55% of FC) when cultivating *Atriplex nummularia* in pots with a harvest at 134 days after
 208 transplanting. As for stem fresh matter, the treatment with 75% of FC was higher than the
 209 others, promoting an increased production. The authors obtained a 90.95 g plant⁻¹ of LFM for
 210 the treatment with 95% of FC, ten times lower than that obtained in this study for 100% of
 211 FC, which was 944.65 g plant⁻¹. This is because the authors harvested saltbushes at 134 days
 212 after transplantation, that is, the period of the first cut, which differs from the present study

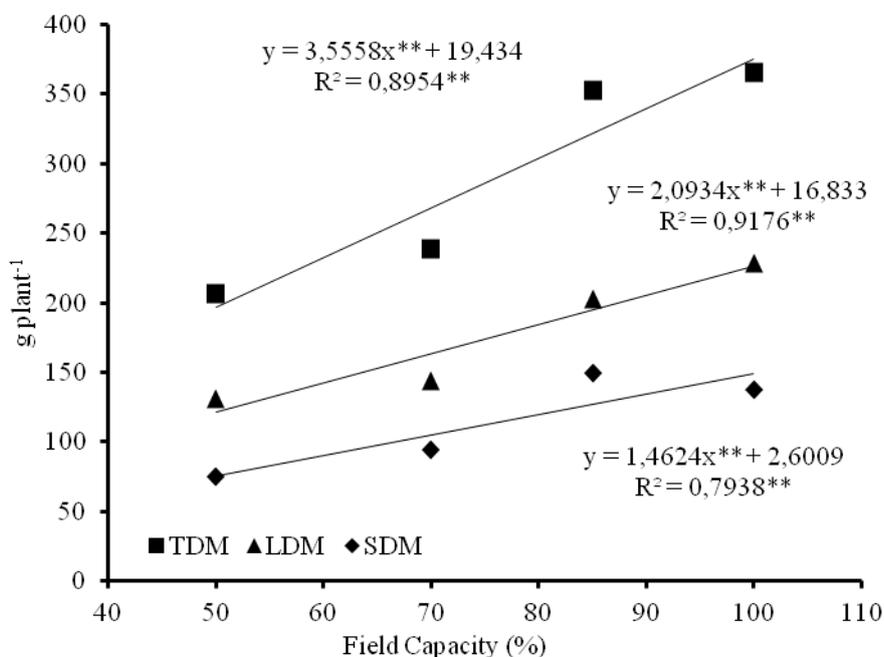

213 where data were obtained from a second cut three months after the first cut, the period when a
214 greater stimulus to the regrowth of branches occurred.

215 These results show that *Atriplex nummularia*, under the conditions to which it was
216 submitted during the study, barely reduced its yield with soil moisture kept at 85% of FC,
217 proving its ability to tolerate water stress at this level. This represents an adaptive advantage
218 of this species regarding the local climate and in terms of the effect of the frequent droughts.
219 It is therefore an alternative to forage production for small farmers given its possibility to be
220 used as a forage species.

221 The behavior of Dry Matter was similar to that of Fresh Matter (Figure 3). LDM was
222 superior to SDM for all treatments. Regarding LDM, the reductions were 36.99 and 42.71%
223 in T₃ and T₄, compared to the control, respectively, while, for T₂, the decrease in LDM was
224 11.09%. In any case, it was observed for TDM that the difference between T₁ and T₂ was only
225 3.54% or less. The obtained productions were 365.44 and 352.51 g plant⁻¹ respectively.

226 For SDM, treatment T₂ (85% of FC) had a value higher than the control treatment
227 (100% of FC), corroborating the results of Souza et al. (2012), who obtained a higher value
228 for this variable for a treatment with 75% of FC compared to the control (95% of FC).

229
230

231

232 **Figure 3.** Linear regression equations relating Leaf Dry Matter (LDM), Stem Dry Matter
 233 (SDM) and, Total Dry Matter (TDM) of saltbush irrigated with waste from desalination
 234 differing in soil moisture level.

235

236 By extrapolating the results of saltbush production of TFM and TDM, considering the
 237 spacing used (1.5 x 1.5 m), the values of yield were obtained in kg ha⁻¹ and in kg ha⁻¹ year⁻¹
 238 (Table 3).

239

240 **Table 3.** Total yield based on Total Fresh Matter (TFM) and Total Dry Matter (TDM) of
 241 *Atriplex nummularia* irrigated with waste from desalination.

Treatment	Total Yield			
	----- kg ha ⁻¹ -----		----- kg ha ⁻¹ year ⁻¹ -----	
	TFM	TDM	TFM	TDM
T ₁	5689,62	1624,00	22758,49	6496,00
T ₂	5363,07	1566,56	21452,30	6266,24
T ₃	3564,92	1059,05	14259,69	4236,19
T ₄	3126,08	915,41	12504,31	3661,65
Average	4435,92	1291,25	17743,69	5165,02

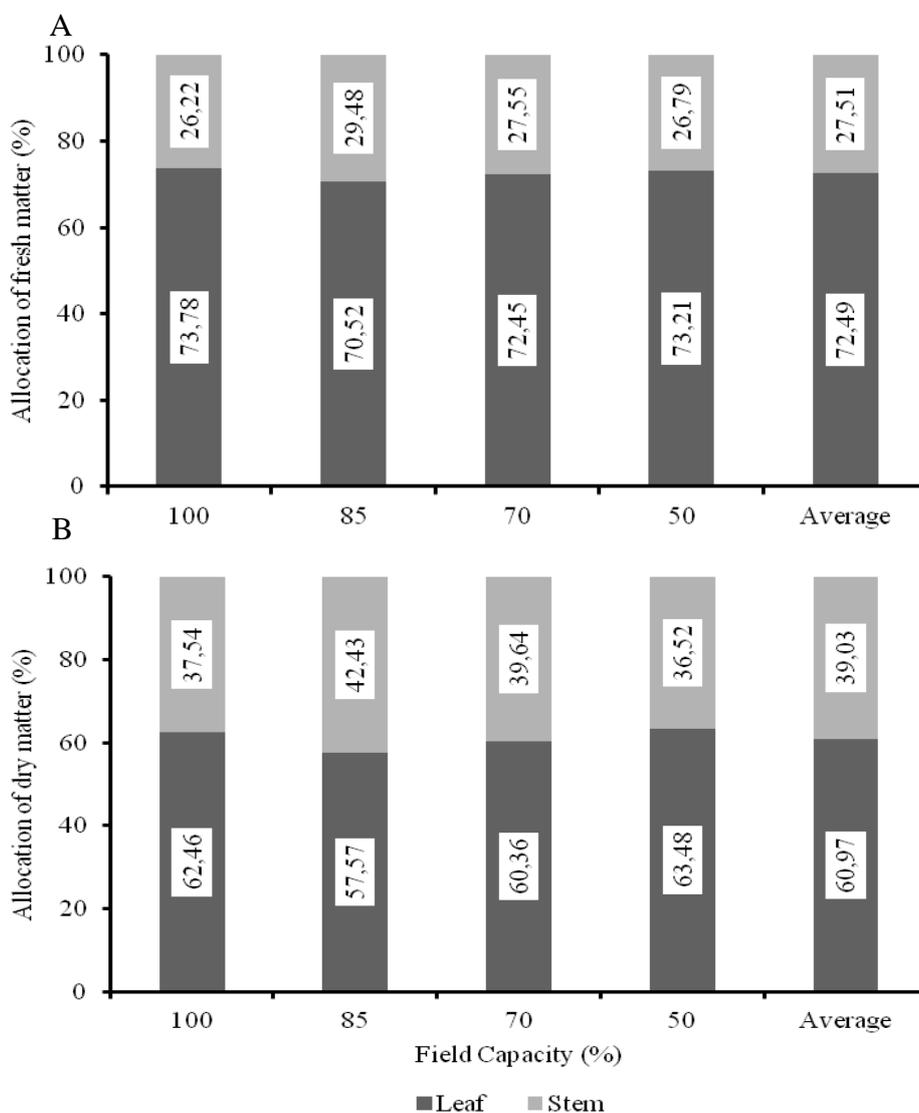

242

243 The productivity reached 5,689.62 and 1,624.00 kg ha⁻¹ of FM and DM respectively for
 244 the treatment at 100% FC while the extrapolated yield for one year was 22,758.49 and
 245 6,496.00 kg ha⁻¹ year⁻¹ for FM and DM respectively in the same treatment. These values are
 246 very close to those obtained by Porto et al. (2006), who obtained 21,296.00 kg ha⁻¹ year⁻¹ of
 247 FM and 6,537.00 kg ha⁻¹ year⁻¹ of DM considering saltbush forage irrigated with 75 L of
 248 wastewater from desalination per plant per week. According to Porto et al. (2006), saltbush
 249 yields normally ranged from 5 to 15 Mg ha⁻¹ year⁻¹ of dry matter, and most of the results were
 250 between 6 and 8 mg h⁻¹ year⁻¹, thus corroborating this study. This is considered a result
 251 compatible with several other forages irrigated with water adequate for irrigation, such as
 252 alfalfa. Barroso et al. (2006), using effluents from tilapia breeding to irrigate *Atriplex*,
 253 obtained yields higher than in this study by varying the volume of effluent applied from 75 to
 254 300 L per week per plant, reaching a maximum productivity of 11,416.0 kg ha⁻¹ year⁻¹ of
 255 forage DM.

256 Considering the local climate under the environmental perspective of reusing waste
 257 from desalination, the results of this study point to *Atriplex nummularia* as a potential
 258 alternative to deposit waste, providing small producers with the possibility of producing
 259 forage during droughts using low-quality water since the saltbush's ability to produce forage
 260 under water stress was very evident in this study.

261 The allocation of Fresh Matter occurred more in leaves (72.49%) than in stems
 262 (27.51%), showing a greater production capacity of the leaf forage fraction in comparison
 263 with stems (Figure 4A). Considering Dry Matter, the proportion of stems increases to 39.03%,
 264 proving the importance of this forage fraction in the final composition of dry matter (Figure
 265 4B).

266
 267

269

270 **Figure 4.** Allocation of Fresh (A) and Dry Matter (B) of saltbush on leaf and stem forage
 271 fractions differing in soil moisture level.

272
 273 The forage fractions analyzed, leaf and stem, were not very sensitive to water levels in
 274 the soil to which they were submitted since, among bromatological composition variables,
 275 only DM suffered a significant effect ($P > 0.05$) regarding the stem. For the leaf fraction,
 276 except for CP, all other variables were significantly influenced by soil moisture. The
 277 fertilization did not significantly affect any of the variables analyzed for leaves and stems
 278 (Table 4).

279
 280

284
 285 The levels of crude protein (CP) in the leaves were, for all treatments, close to 15%
 286 (Table 5), showing that saltbush has good forage quality. These values are in agreement with
 287 those obtained by Barroso et al. (2006), who obtained a maximum of 15.79% at 12 months
 288 after planting, values above the values obtained by Watson and O'Leary (1993).

289 On the other hand, Porto et al. (2001) reported mean levels of CP of leaves of 18.7%
 290 and 18.5% respectively, confirming that saltbush leaves hold good levels of crude protein,
 291 levels that may be compared with those of some legumes and other species often used in
 292 animal feed, such as *Leucaena*, *Gliricidia*, forage guandu pea and maniçoba, which in general
 293 have between 12 and 22% of crude protein (CARVALHO JUNIOR et al., 2010). As for the
 294 stem, the CP content was lower if compared to leaves (Table 5) and below the values obtained
 295 by Barroso et al. (2006).

296 Overall, CP results show relevant *Atriplex* characteristics as forage even under low soil
 297 moisture conditions, allowing use of it in feed for livestock in areas frequently lacking rain,
 298 such as the Brazilian semiarid region, since the critical content for animal consumption is 7%
 299 of CP in dry matter. For a good performance of lactating cows, forage should contain
 300 approximately 15% of CP; for growing animals, the 11–12 % level is acceptable.

301

302 **Table 5.** Crude Protein (CP), Mineral Matter (MM), Organic Matter (OM) and Dry Matter
 303 (DM) of saltbush leaves (*Atriplex nummularia*) at 3 months after cutting.

Treatments	-----Leaf-----				-----Stem-----			
	CP	MM	OM	DM	CP	MM	OM	DM
T ₁	14,36	30,53	69,47	22,20	4,99	8,98	91,02	36,74
T ₂	14,77	30,34	69,66	21,76	4,72	9,04	90,96	38,09
T ₃	15,31	29,84	70,16	22,74	4,72	8,95	91,05	39,01
T ₄	15,11	29,65	70,35	23,04	6,22	9,24	90,76	35,83
Average	14,89	30,09	69,91	22,43	5,16	9,05	90,95	37,42

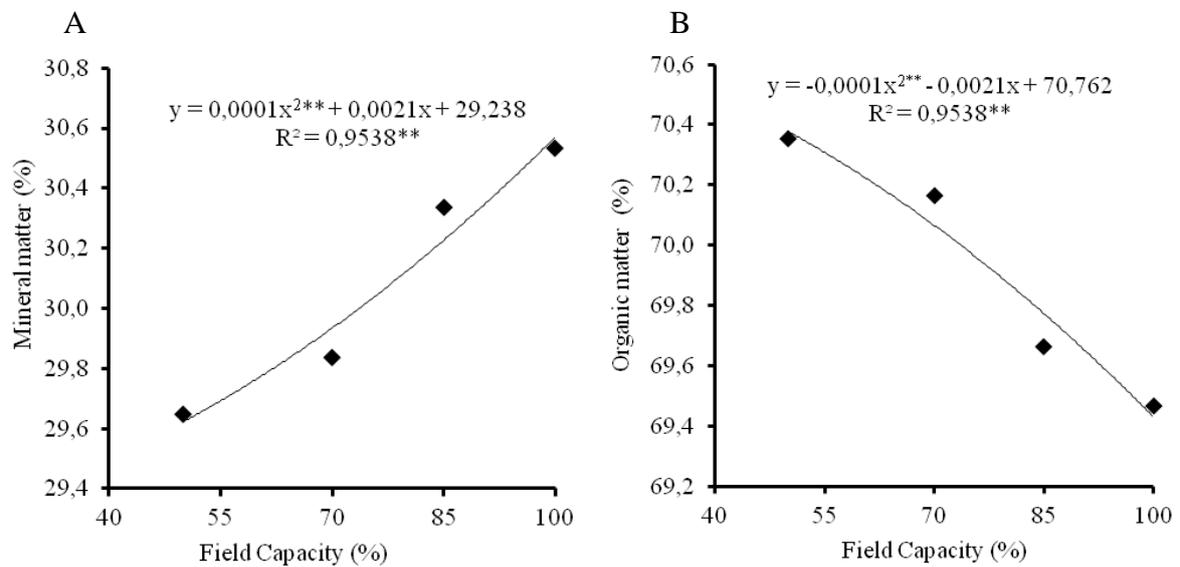

304

305 The Mineral Matter (MM) content was high in leaves (Table 5), showing a quadratic
 306 effect for this variable in the treatments (Figure 5A). The soil kept at 100% FC (T₁) had a
 307 higher MM content (30.53%), confirming the enormous capacity of *Atriplex* in extracting soil
 308 salts, which is the main factor that provides the elimination of salts. Moreover, this extensive
 309 salt accumulation capacity in the leaf tissue is considered as a major limitation of the use of
 310 saltbush as forage, it being necessary to limit the proportion of saltbush in the composition of
 311 animal feed since higher ratios may lead to rejection of the plant by the livestock.

312 Souto et al. (2005), providing sheep with a diet containing 38.30% of saltbush hay,
 313 provided an average daily gain of 145 g/day to animals. The leaf OM suffered a quadratic

314 effect, behaving inversely to MM, in the treatment with the lowest soil moisture (T₄). It had
315 the highest proportion of OM (70.35%) (Figure 5B).

316

317

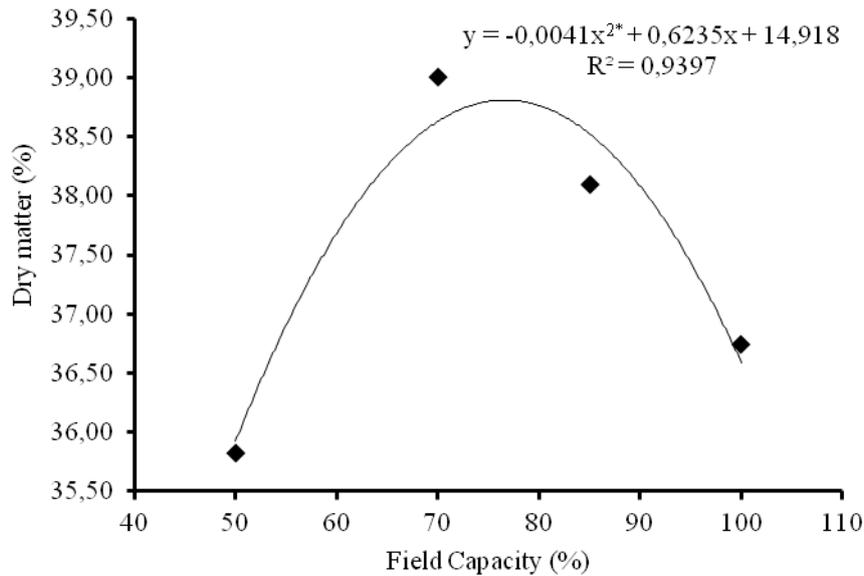

318 **Figure 5.** Regression equations relating Mineral Matter (MM) (A) and Organic Matter (OM)
319 (B) of saltbush irrigated with waste from desalination differing in soil moisture level.

320

321 Regarding the stem, OM levels were above 90% for all treatments (Table 5). These data
322 are in agreement with those obtained by Carvalho Junior et al. (2010). As for the DM of
323 leaves, it decreased as the soil moisture in treatments increased. This is the opposite effect to
324 that observed for stem DM where T₂ and T₃ were higher (Figure 6). However, the values for
325 leaves were lower than the values obtained for stem DM (Table 5). Leaf and stem DM values,
326 similar to those obtained in this study, are presented in Porto et al. (2001).

 331 waste from desalination differing in soil moisture level.

332

333

334 CONCLUSIONS

335

336 Saltbush fresh and dry matter production with an 85% soil moisture level in relation to
 337 field capacity had the minimum loss of yield, being productive even in the driest soil.

338 The total yield, fresh and dry, was satisfactory using the waste from desalination for the
 339 irrigation of saltbush, proving its viability for the production of forage.

340 The *Atriplex nummularia* showed a good bromatological quality for all treatments,
 341 especially in relation to crude protein.
